AI Assistance Summary

COMP3211 Group 149 PIM | Prepared 20 October 2026

This summary records assistance visible in this project session. Students must review it, add any other assistance actually used, and transfer accurate information into the course's official Honour Declaration for Group Project. This document does not replace that form, attest student contributions or provide a signature. No student identity, contribution percentage or signature has been supplied or invented here.

Assistance provided

OpenAI Codex assisted with reading and comparing the project specification, the user-selected SRS v1.3 and merged design v1.1; preparing and maintaining the implementation plan; and recording routine implementation choices and source qualifications. The user supplied the project constraints, selected the SRS baseline, approved the working plan and authorized the implementation stages.

Codex generated and revised Python source for immutable records, validation, exceptions, search/Composite criteria, saved criteria, collection service, strict JSON persistence, terminal parsing/view/controller and the main entrypoint. It generated automated tests, ran tests and actual CLI workflows on the available macOS environment, investigated failures and fixed the long-expression evaluation crash. It prepared and validated the standard-library model line-coverage tool, including unexecuted-module accounting and trace-hook recovery.

Codex also prepared README, developer/user manuals, requirements and model line-coverage reports, illustrative sample files, demo commands/recording checklist, Windows verification checklist, handoff status and this summary. Document-generation tools were used to create and inspect PDF/Word artifacts. The handoff specification copies incorporate the user's explicit permanent-EOF clarification; original source documents are preserved.

These materials contain substantial AI-assisted code, tests and text. Students should not describe them as wholly unaided work. Local test results and process evidence come from actual executions; coverage is measured rather than inferred. Their presence does not certify independent student review.

What was not performed or established

No real Windows verification, implementation MP4, presentation recording, student contribution allocation or signature was created. No instructor confirmation of the provisional alarm scope has been obtained in this session. No repository commit, push or publication was authorized or performed. Windows instructions and IDE steps are not claimed executed merely because they are documented. Student recording and declaration tasks remain outstanding.

Students complete the official process

Obtain the official course form and follow its current fields/instructions. Review every assisted artifact for correctness, understanding and acceptable use. Describe the actual scope of assistance, including any other tools or sessions. Agree genuine contribution percentages among group members and enter the required identities, attestations and signatures yourselves. Resolve disputes through the instructor's process rather than inventing values.

Include the genuinely completed Honour Declaration at the final ZIP root, as required by Project Description page 3. Retain this summary as supporting information if appropriate; a blank or unsigned substitute is not completion.
